SUMMARY A girl with retinoblastoma and a del(13)(q13q14·3) is presented. This case helps to confirm and extend our previous observations' regarding a recognisable facial pattern in retinoblastoma patients with 13q deletion involving 13q14 and its adjacent segments.

The proband, a girl (fig 1), was the second child of non-consanguineous parents. Both parents and an older brother were in good health. The mother was 26 and the father 32 years old at the time of her birth. The family history was negative for retinoblastoma or congenital malformations. The mother had no previous miscarriages. Pregnancy was complicated by hyperemesis requiring infusion therapy and threatened abortion. Delivery was normal and at term. Birth weight was 3742 g and length 55 cm. At one month bilateral leukokorias were noted. At two months enucleation of the left eye was performed after the clinical diagnosis of bilateral retinoblastoma at another eye clinic. Shortly after this surgery, she was referred to our hospital for conservative therapy to the tumour in the right eye. Linear X irradiation (total 3600 rads) and subsequently systemic vincristine and cyclophosphamide were started.

Physical examination showed the following findings: brachycephaly with bilateral parietal bossing, hirsute forehead, upward slanting palpebral fissures, broad nasal bridge, bulbous tip of the nose with anteverted nostrils, long philtrum, thin upper lip, large ears with folded lobule and multiple postauricular pits, and widely spaced nipples. She had normal muscle tone. She began to vocalise with her mother at three months and the developmental quotient at nine months of age was 87. Anthropometric measurements at nine months of age were: weight 8·15 kg (−0·4 SD), height 69·6 cm (−0·3 SD), chest circumference 42·5 cm, and head circumference 44·5 cm.

Fingertip patterns showed UWWWW on the right and all whorls on the left, with a total finger ridge count of 145. The palm showed a vestige in the thenar area, bilaterally. The atd angle was 45° bilaterally.

FIG 1 The proband aged three months with a prosthesis in the left orbit.

Received for publication 20 October 1986.
Accepted for publication 11 December 1986.
The present Discussion 46,XX,del(13)(ql3 or at somestitial deletion were obtained respectively. All chromosome 13 was observed in three of our six patients and large ears with folded lobules were observed in all six in our study. Postauricular pitting, which Crowder et al6 described as a unique feature of 13q deletion involving 13q14, was observed in three of our six retinoblastoma patients with 13q deletion. Further accumulation of cases of retinoblastoma with 13q deletion with full description of phenotypes will be required in order to delineate 13q deletion syndrome with retinoblastoma further.

We are very grateful to Dr H Hayakawa for reviewing the manuscript.
