### Syndrome of the month

**Aarskog syndrome**

**Mary E M Porteous, David R Goudie**

Aarskog syndrome (facio-digital-genital syndrome) was first described in 1970 by Dagfin Aarskog who presented seven males from one family with a growth disorder and associated anomalies. A year later Scott reported three brothers with similar features and since then there have been over 100 cases published. We are aware of 12 subjects with Aarskog syndrome living in the west of Scotland (population 1.6 million). However, owing to the benign nature of the condition, it is underdiagnosed and the true incidence must be higher than this.

**Inheritance**

Aarskog syndrome has been assigned to the X chromosome on the basis of pedigree analysis but this interpretation remains open to doubt. The importance of shawl scrotum as a clinical feature produces a diagnostic bias in favour of males. The facial features are often as obvious in female carriers as in male carriers, and in two large pedigrees male to male transmission has been found.

In 1984, Bowle et al. described a mother and son with Aarskog syndrome and an X;autosomal translocation (Xq13;8p21.2). In the absence of linkage data to clarify the issue, the disorder is as likely to be a partially sex limited autosomal dominant localised by the autosomal element of the translocation.

**Clinical features**

The table summarises the main clinical features found in Aarskog syndrome and compares the 17 males in the Glasgow series with those published previously.

**Clinical features in Aarskog syndrome.**

**FACES**

Boys with Aarskog syndrome are strikingly similar in facial appearance. Fig 1 shows two unrelated boys with Aarskog syndrome and fig 2 shows three brothers with the syndrome. Carrier females may exhibit many of the facial features (fig 3).

The cardinal features are hypertelorism, a widow’s

peak, ptosis, downward slanting palpebral fissures, small, short nose with anteverted nares, a broad nasal bridge, maxillary hypoplasia, abnormal auricles, a wide philtrum, and a crease below the lower lip. Fig 4 shows the evolution of the facial phenotype through time.

SKELETAL
Short stature in Aarskog syndrome is disproportionate, with an increased upper to lower segment ratio. The hands are short and broad with brachydactyly, syndactyly, clinodactyly, particularly short fifth fingers with single creases, single palmar creases, and striking joint laxity particularly evident in the phalanges (fig 5).

Other skeletal abnormalities which have been documented are odontoid hypoplasia with cervical
Porteous, Goudie

ligamentous laxity, scoliosis, metatarsus adductus, and splayed toes with bulbous tips.

GENITAL
The characteristic abnormality in Aarskog syndrome is the shawl or overriding scrotum, though this need
not be a constant feature. It becomes much less obvious with age. Cryptorchidism is common as are inguinal herniae. If the cryptorchidism is corrected early, fertility is unimpaired.

GROWTH
The majority of males with Aarskog syndrome are short, usually below the 10th centile and often below the 3rd. Infants have a normal birth weight but growth falls away across the centiles over the first year. Children remain very small until they enter puberty. Puberty is often delayed but inevitably occurs bringing with it a prolonged growth spurt.

INTELLIGENCE
Subjects with Aarskog syndrome can be expected to have normal intelligence when allowance is made for the ascertainment bias associated with recognition and reporting of handicap in dysmorphic syndromes, and the fact that a number of reported cases with mental

Aarskog syndrome

handicap do not satisfy the diagnostic dysmorphic criteria. The proportion of mentally handicapped persons does not show a statistically significant excess over that in the general population, although the sample size is too small to exclude positively an association with mild learning difficulties.

VISION
There is an increased incidence of hypermetropia in persons carrying the gene for Aarskog syndrome.

LIFE EXPECTANCY
Aarskog syndrome is associated with a normal life span.

Differential diagnosis
The differential diagnosis of Aarskog syndrome includes Noonan syndrome and Robinow syndrome. Aarskog syndrome is not associated with heart defects or major genital abnormalities and caution should be exercised before making a diagnosis of Aarskog syndrome if they are present.

We would like to thank Dr John Burn for introducing us to the Newcastle family and for his comments on this manuscript. We also thank the families involved for all their help. M Porteous was in receipt of an MRC grant at the time that this work was carried out.
