Heterogeneity of sickle cell anaemia in Arabs: review of cases with various amounts of fetal haemoglobin

KARIM KAMEL

From the Department of Pathology and Blood Transfusion Service, The Military Hospital, UAE Armed Forces Medical Services, Abu Dhabi, United Arab Emirates

SUMMARY A study is presented on eleven patients with homozygous sickle cell anaemia. They are non-Sheeah Arabs from the United Arab Emirates on the south-eastern coast of the Arabian Peninsula. The proportions of fetal haemoglobin in these patients are variable, and there is a marked variation in the severity of their disease condition; these facts are not related. African sickle cell gene admixture is a likely affecting factor.

In 1972, Perrine *et al.* reported the condition of 'benign sickle cell anaemia' in 18 Arabs. The patients were Saudis of the Shiite (Sheeah) religious sect of Islam from Al Qateef and Al Hasa oases on the eastern coast of the Arabian Peninsula, and the mildness of their disease was ascribed to a high proportion of fetal haemoglobin (Hb F). This was later proved not to be the result of coexistent glucose-6-phosphate dehydrogenase (G6PD) deficiency, α -thalassaemia trait, or hereditary persistence of fetal haemoglobin, but was rather a genetically determined condition of an absolute increase in Hb F production related to their homozygous sickle cell anaemia (Pembrey *et al.*, 1978; Perrine *et al.*, 1978).

This is a presentation of another group of sickle cell anaemia patients in non-Sheeah Arabs of nearby Abu Dhabi, capital of the United Arab Emirates (UAE) on the south-eastern coast of the Arabian Peninsula. Some of the patients reviewed here also have increased Hb F production, and some do not, and the heterogeneity of their clinical and haematological conditions is manifest.

Materials and methods

The subjects, eleven in number, are Arabs and their families have lived in this part of the world for as long as they know. They are not Sheeah. The patients are dependants of military personnel who were referred to the Haematology Division of the Pathology Department of the Abu Dhabi Military Hospital for haematological assessment over the last 4 years. This Division serves patients, both military

and civilian, with haematological problems from the seven Emirates that make up the Federal Union.

The following determinations were carried out on all the patients and on both parents of each patient, Nos 1, 3, 5, 8, 9, and 11 (Table). The rest of the parents could not be examined. The tests were complete blood counts including reticulocyte count, haemoglobin electrophoresis on cellulose acetate medium in tris EDTA borate buffer at pH 8.6, sodium metabisulphite sickling preparation, done by standard techniques (Dacie and Lewis, 1975), and solubility test for Hb S using a commercial kit (Sicklelex). Alkaline denaturation test for Hb A₂ was made by the method of Singer *et al.* (1951). Hb A₂ was estimated by the technique of Weatherall and Clegg (1972), a modification of that of Marengo and Rowe (1965). Screening for G6PD deficiency was performed by the UV fluorescent spot test of Beutler (1966) using Sigma ready reagents.

Table Haematological and clinical data on 11 non-Sheeah Arabs with sickle cell anaemia

Case No	Age (y)	Sex	PCV range* (%)	Hb range* (g/dl)	Hb F (%)	Crises (per year)	Reticulocytes (%)
1	5	F	19-27	5.9-7.8	8	3-5	4-36
2	18	M	31-36	10.6-12.0	14	3-5	5.6-8
3	19	M	24-32	7.2-10.6	11	2	2-4
4	20	M	36-39	12.3-12.9	15	3	4-6
5	21	M	28-33	9.4-11.1	18	2-3	12
6	19	M	32-34	9.9-10.4	10.9	0-1	19
7	20	M	33	11.4	12	3-5	3
8	8	F	26-28	7.0-7.4	13	0-1	4
9	10	M	20-23	5.6-8.0	8	4	4
10	6	F	30	9.5	9	0-1	6
11	7	F	26-36	7.8-10.8	12	2-3	4.6-8.8

*Where only one value is given, the patient could not be examined more than once.

Received for publication 23 March 1979

Results

The results of the above determinations are given in the Table. G6PD deficiency was excluded in all subjects tested, and Hb A₂ was within the normal range in them all.

Discussion

All patients had homozygous sickle cell anaemia with Hb type SS + F and the tested parents had sickle cell traits with Hb A + S. G6PD deficiency in Abu Dhabians is expressed by a *Gd*⁻ gene frequency of 0.1000 and they are usually symptomless (Kamel *et al.*, 1979), either because of a genetic determination or because of the absence of the challenging oxidant. It was not a superadded factor in the patients reported here, since none was G6PD deficient by the screening test.

The prevalence of some thalassaemia syndromes is high in certain Saudi Arabs (Pembrey *et al.*, 1975). In the present population, the incidence of various thalassaemias is not known. It is of significance, however, that over the last 4 years, only two cases of classical β -thalassaemia major were confirmed in this department among the indigenous population. One of these was from Abu Dhabi Emirate, and the other was from Um Al-Quwain Emirate, with populations of about 80 000 and 10 000, respectively (Ramahi, 1973). Hb A₂ was not raised in any of the people reported here, and a survey on Hb variants only showed Hb S among Abu Dhabians (Kamel *et al.*, 1979).

It is worthy of note that in three of the eleven patients (No 1, 8, and 9), the haemoglobin (Hb) level had stabilised at less than 8.0 g/dl, and that in another two cases (No 3 and 11) the Hb level was often below 8.0 g/dl. The number of crises or infections or both necessitating admission to hospital varied from 0 to 5 per year, and two cases (No 1 and 9) required transfusions at least once a year. It is interesting that patients No 4 and 9, in addition to their sickle cell anaemia, had *Plasmodium falciparum* infection. Four patients (No 2, 4, 5, and 7) at some time had a Hb level over 11.0 g/dl without transfusion and thus did not qualify at those times for the diagnosis of anaemia as defined by the World Health Organization in 1968. Two cases (No 6 and 10) were moderate in severity at a Hb level ranging from 9.5 to 10.4 g/dl. None of the patients had leg ulcers nor scars from them.

Hb F ranged from 8 to 18% with a mean of 11.9% and within this range there was no correlation between its level and the patients' clinical manifestations. Hb F percentage in the reported patients falls mid-

way between that of the Sheeah and Jamaican levels (Perrine *et al.*, 1972).

The patients presented here have been 'selected' in that they were referred patients and their number is obligatorily small because of the small Abu Dhabian population and the relatively low frequency of Hb S gene of 0.0120 (Kamel *et al.*, 1979). They nevertheless illustrate the presence of a wide range of severity of clinical manifestations of homozygous sickle cell anaemia in some Arabs who also have varying amounts of Hb F. However, this series should not imply the non-existence of very mild cases of benign sickle cell anaemia patients in the same community who did not come for haematological advice. Four of the eleven patients should indeed be classified as benign.

The Sheeah, the sect of Islam introduced in Iraq in the 7th century, only predominate in Iran, Iraq, Pakistan, and Bahrain. Elsewhere in the Islamic nations, the overwhelming majority are Sunnis. Some Hinnawi tribes in the Sultanate of Oman, which is adjacent to the UAE, are of the Ibadhi sect, differing from both Sunnis and Sheeah (Phillips, 1971). Except where mentioned above, the Sheeah are clustered in isolated foci forming good opportunities for inbreeding. This may have been a causative factor in the abundance of benign cases of sickle cell anaemia reported.

Although the patients reviewed here are Arabs in origin, intermixing with African sickle cell gene is a likely event since (1) there is debate about whether the sickle cell gene originated in Africa or Asia (Kamel and Awny, 1965); (2) the slave trade market (from Africa) was a flourishing business until the British treaties with the Trucial Coast authorities between 1839 and 1856 (Abdullah, 1978); and (3) the Coast of Oman (later called the Trucial Coast) historically dominated most East African territories and islands.
