circumference of 58.5 cm and the absence of neurological findings.\textsuperscript{5}

Discussion

With the present report there are now four instances of familial recurrence of congenital short femur. Ring\textsuperscript{2} described a pair of concordant twins with congenital short femur in 1959, but no comment was made about their zygosity. Kelly\textsuperscript{3} noted that a third degree relative had a curved femur, and in his comprehensive family study Hamanishi\textsuperscript{4} found only one familial recurrence in first cousins among 56 families studied. In this study,\textsuperscript{4} no raised parental ages were found and only one set of parents was consanguineous. Furthermore, three sets of discordant twins of uncertain zygosity have been reported.\textsuperscript{5} 6

With the exception of thalidomide, which is usually associated with more severe femoral defects, no consistent environmental factors have been identified. Unifactorial inheritance is most unlikely with the observed patterns of familial recurrence and twin concordance favour multifactorial inheritance for simple femoral hypoplasia.

We wish to thank the Wellcome Trust and the National Fund for Research into Crippling Diseases for financial support.

Poland syndrome associated with ‘morning glory’ syndrome (coloboma of the optic disc)

D T PIŠTELJIĆ*, D VRANJEŠEVIĆ*, S APOSTOLSKI†, AND D D PIŠTELJIĆ*

*Institute for Neurology and Psychiatry of Childhood and Adolescence, and †Clinic for Neurology, 11000 Belgrade, Yugoslavia.

SUMMARY A 12 year old girl with the Poland syndrome and the ‘morning glory’ syndrome is described. The patient presented with absence of the left pectoralis major muscle, hypoplasia of the left arm, symbrachydactyly, and ipsilateral coloboma of the optic disc. This is the first report of the association of these two congenital anomalies.
Poland syndrome consists of absence of the sternal portion of the pectoralis major muscle and symbrachydactyly. The 'morning glory' syndrome or coloboma of the optic disc is thought to result from disturbances in closure of the embryonal optic fissure. Congenital malformations of the optic disc are seldom specifically distinguishable without histological examination, but they are usually represented by specific clinical findings. We report a patient with a combination of these abnormalities involving the same side.

Case report

The patient was a 12 year old girl with signs of Poland syndrome on the left side and coloboma of the left optic disc. The family history was negative for both anomalies.

Aplasia of the sternal portion of the left pectoralis major muscle was associated with hypoplasia of the breast and nipple and reduced axillary hair (fig 1). The left arm was thinner and 2.5 cm shorter than the right. The middle phalanges of the fingers of the left hand were missing (symbrachydactyly) (fig 2).

The right eye was myopic with a visual acuity of 6/6 -10-0. The left eye was blind, divergent, and raised. The visual field and colour perception were normal in the right eye and intraocular pressures were normal. The appearance of the right fundus was normal but the left fundus showed features of the 'morning glory' syndrome (fig 3). Fluorescein angiography indicated normal duration of retinal blood vessel filling on both sides. ERG was normal on the right but subnormal for the left eye.

Neurological, neuroradiological, neuroendocrinological, and EEG examinations revealed no abnormalities. Antibody titre measurement showed no antibody production against CMV, rubella, HSV1,
and HSV₂ viruses. The karyotype was 46,XX (in five cells).

Discussion

Poland syndrome is often associated with other congenital abnormalities: hypoplasia of the breast and nipple, reduced axillary hair, anomalies of the bony thorax, syndactyly, cleft hand deformities,³ preaxial polydactyly type 1, absence of extensor tendons of the hand and hypoplastic thenar muscles,⁴ dextrocardia,⁵ skeletal and genitourinary tract abnormalities.⁶ It has also been associated with Möbius⁷ and Pierre-Robin⁸ syndromes.

‘Morning glory’ syndrome is usually a unilateral congenital defect that occurs as a consequence of developmental disturbance of the optic disc in the course of the first six weeks of gestation and is accompanied by severely impaired or completely absent vision. This syndrome has been associated with basal encephalocele⁹ ¹⁰ and Duane’s retraction syndrome.¹¹

The aetiology of ‘morning glory’ syndrome and the nature of its association with Poland syndrome remain unclear.

Interstitial deletion of chromosome 4q diagnosed prenatally
