Dyskeratosis congenita: three additional families show linkage to a locus in Xq28

Reynir Arngrimsson, Inderjeet Dokal, Lucio Luzzatto, J Michael Connor

Abstract
Dyskeratosis congenita (DC) is a rare inherited disorder with most families being of the X linked recessive type. We describe three families which show linkage to the marker DXS52 on Xq28. The combined maximum lod score was 2.00 at zero recombination. This is further evidence that the X linked DC gene is located at Xq28 and brings the reported maximum lod score for DC and DXS52 to 5.33 at zero recombination fraction, with a supporting recombination fraction interval of 0-00-0-10.

Subjects and methods

Patients (Fig 1)
Family 1 has been described in detail by Dokal et al.1 The proband first presented with symptoms of DC at the age of 29 years. His younger brother was diagnosed when he was 26 years old, while being assessed as a potential bone marrow donor.

Patient 3 is a nephew of patients 1 and 2. He was investigated at the age of 12 years and the diagnosis of DC was made. An older half sister of the proband had two sons, who showed no signs of DC on clinical examination and laboratory investigation. Their phenotype was assigned as normal.

Family 2 is a South African family and has been described in detail by Jacobs et al.2 Three boys and their maternal grandfather were diagnosed as having DC. The grandfather and two of the affected boys were dead, leaving one affected boy, his mother, and two normal brothers available for this linkage study.

In family 3 the proband, of British origin, was diagnosed as having DC. His uncle had died earlier of pneumonia and was noted to have nail dystrophy. The proband, his normal brother, and mother, who is an obligate carrier, were available for linkage analysis.

DNA studies
DNA was extracted from leucocytes using standard methods and 5 to 10 μg of DNA were digested overnight using Taql enzyme (NBL) under conditions defined by the manufacturer. Restriction fragments were separated in 0-8% agarose gels and transferred by Southern blotting9 to Hybond–N (Amersham).

The probe used was DXS52 (St14.1),10 which is multiallelic with a PIC value of 0-77, and is a reference marker for Xq28. The probe

was labelled with \(^{32}\)P either by nick translation\(^1\) or by oligonucleotide labelling.\(^2\) Hybridisation was performed overnight at 42°C in hybridisation buffer as follows: 50% formamide, 1 X Denhardt’s, 5 X SSC, 20 mmol/l NaH\(_2\)PO\(_4\), pH 6.8, 0.1 mg/ml heat denatured salmon sperm DNA, 0.02 mg/ml poly(A), and 10% dextran sulphate. Non-specifically bound probe was removed by washing in 1 X SSC, 0.1% sodium dodecyl sulphate (SDS) followed by 0.5 X SSC, 0.1% SDS, both at room temperature, and finally one or two washes in 0.1 X SSC, 0.1% SDS at 65°C. Bands were visualised by autoradiography for one to seven days at ~80°C using intensifying screens.

Lod scores were calculated using the computer program LIPED.\(^3\) In these calculations a disease allele frequency of 0.01 was used, and complete penetrance was assumed for hemizygous males. The supporting interval was estimated by finding the recombination fraction at the lod score which was one unit lower than the maximum lod score.

Results

Pairwise linkage analysis showed no recombination between the locus for DC and RFLPs identified by DXS52 in all three families. A combined maximum lod score of 2.00 was observed at zero recombination fraction (table 1).

These results bring the total lod score for DC and DXS52 to 3.33 at zero recombination (table 2). The supporting recombination interval is 0.00-0.10.

Discussion

Linkage analysis in one large family using multiple X chromosomal DNA polymorphisms has previously assigned the gene for X linked recessive dyskeratosis congenita to Xq28.\(^4\) Another family showed cosegregation of DC and G6PD deficiency\(^5\) which also maps to Xq28. Only one recombination between DC and G6PD was observed among nine post-pubertal males. This study was, however, limited as the assay only allowed the genotypic of the females to be assigned on the basis of their offspring’s phenotypes.

The present study supports tight linkage between DC and loci on Xq28 and raises the maximum lod score for DXS52 from 3.33 previously described\(^6\) to 5.33 (table 2). These results will allow further testing of other kindreds to identify genetic heterogeneity which has been suggested on the grounds of clinical and pedigree data.

The authors would like to thank Professor N Saxe, Department of Dermatology, Groote Schuur Hospital, Cape Town, Professor P Brighton, Department of Human Genetics, University of Cape Town, Dr D Osier and Dr J Hows, Royal Postgraduate Medical School, Hammersmith Hospital, London, for providing clinical information on the families used in this study.
