Deletions of the entire APC gene are associated with sessile colonic adenomas

Lynch et al have recently described four extended kindreds with an autosomal dominant inherited predisposition to cancer characterised by multiple colonic adenomas. The affected members of each family were usually fewer than 10 in number, proximally sited in the colon, and often flat or sessile rather than polypoid. Linkage analysis using DNA markers for loci flanking the APC gene in two of the families showed linkage to the APC gene locus with a multipoint lod score of >3. A similar large family with variable numbers of colonic adenomas in affected persons was described by Leppert et al in 1990, where linkage between the disease and the APC locus was shown, with a lod score of 5.58.

The flat adenoma phenotype is of clinical importance since these adenomas may be difficult to define at endoscopy, and because of their predominantly proximal location, colonscopy rather than sigmoidoscopy would be required to detect them. The histology of these lesions is distinct from the classical polypoid lesion of FAP.

At Lynch's suggestion, we have reviewed our series of the colonic adenomas detected in the two cases of FAP with cytogenetic 5q deletions including the entire APC gene, which we described previously. In both cases, adenomas were predominantly proximally sited in the colon, and in both there were some sessile adenomas, similar to those described by Lynch et al. However, the majority of the adenomas in the case 1 were microadenomas and microadenomas were also found, and the overall histological picture was similar to classical FAP. In case 2, many adenomas in the distal colon were flat, but in the more proximal colon, pedunculated adenomas were seen in increasing numbers to the caecum.

We therefore feel that the heterozygous deletion of the total APC gene is associated not specifically with the phenotype of hereditary flat adenomas, but with a form of FAP characterised by a more proximal distribution of adenomas than usual, with some lesions being sessile and some being non-polypoid or flat. We could postulate that in the usual type of FAP where the mutation results in a truncated protein, this protein could possibly interfere with the function of the normal protein product of the normal allele to cause a more severe disease than seen in our patients.

BOOK REVIEWS

If you wish to order or require further information regarding the titles reviewed here, please write to or telephone the BMJ Bookshop, PO Box 295, London WC1H 9JY. Tel 071 383 6244. Fax 071 383 6662. Books are supplied post free in the UK and for BFPS member addresses. Overseas customers should add 15% for postage and packing. Payment can be made by cheque in sterling drawn on a UK bank or by credit card (Mastercard, Visa, or American Express) stating card number, expiry date, and full name. (The price and availability are occasionally subject to revision by the Publishers.)

By any criteria the Huxley family is incredibly gifted. Julian (1877-1975), the subject of this biography, ranks among the foremost biologists of this century. He had a life long fascination with all things animate. He liked to consider himself a generalist and he certainly had interests in a wide range of subjects. I still remember vividly a lecture he gave to us as undergraduates on the intriguing metamorphosis of the axolotl and the problems of allometric growth and the demise of the Irish Elk. He was also interested in ornithology and his careful and classical studies of the courtship behaviour of the Great Crested Grebe established the new discipline of ethology. He researched marine invertebrates and for a time was employed at the world famous Stazione Zoologica in Naples.

In 1925 he became Professor of Zoology with an annual salary of £1000, a figure income never previously offered to a British biologist! He has often been described as an excellent teacher. In his work he travelled widely. He loved America and in his travels to Africa to advise on education took a great interest in the wild life and conservation. He was elected to be the First Director General of UNESCO in 1946. Subsequently he became involved in the notorious Lysenko affair whose work he ultimately dismissed on scientific grounds. He was a prolific writer and many of his books helped popularise science and the concept of Humanism.

What of the man himself? Huxley's own autobiography (Memories, Vols I and II, Penguin Books) reveals little and the author admits he has been unable to discover very much. Huxley was given to "nervous breakdowns" and reading between the lines of this biography, he had difficulties with close personal relationships. Could the author have divined more by interviewing those who had known and worked with Huxley? I don't know, but as a scientific biography this is an excellent contribution on a great biologist. It is well documented and well written and can be highly recommended.

ALAN EMERY

This is a very nicely produced book comprising 14 chapters, which deal with every aspect of new procedures (largely untried) for diagnosis of genetic disease in human oocytes and embryos in vitro. The book is divided into five sections. Although all the chapters are clear, well written, and interesting, some of them are not relevant to the title of the book and it is therefore a book as a whole is not clear.

The chapters are distributed somewhat arbitrarily into five sections which I will summarise.

The first section contains three introductory chapters which give background – a rambling walk through early attempts to diagnose sperm, oocytes, and embryos (Edwards and Schullman), an excellent review of our knowledge of molecular synthesis in human embryos (Tesarak), and the logistics of the clinical application of preimplantation diagnosis (Penketh). The second section contains a useful overview of genetics of common diseases by Schullman and Black and two chapters, which are out of place in the context of this book, on the history of prenatal diagnosis (Verloes and Ginsberg) and chorionic villus sampling (Pergament and Fine). The third section contains two technical chapters on methods of DNA diagnosis by Bentley et al, which would have been more sensibly organised as one chapter and included in the fourth section which addresses the main theme of the book. The first chapter in this section, "Can Spermatozoa be Typed?" by Gledhill and Edwards, has been answered in part, since Johnson et al (Hum Reprod 1993; 8: 1735) have recently reported fluorescence activated cell sorting of X and Y bearing human sperm. Then follows a condensed chapter on polar body diagnosis by Verlinsky and Strom (more support for the data given is needed here), another review of blastomere biopsy and sexing by Handside and Delhanty, a fascinating and informative review of the blastocyst and blastocyst biopsy by Harthorne et al, and a survey of the potential of new screening approaches by Leese and Edwards. Finally, there is a most welcome review of the ethical and legal aspects of the work by BraAMS.

Overall, if you are interested in this rapidly developing field, this book is comprehensive and "intended to be an up-to-date presentation". However, as is always the case in edited volumes of this type, chapters are prepared well before the final publishing date and inevitably the claim to "the latest technology" cannot be upheld. In this year, we have seen significant developments of the Boyce typing, the preimplantation diagnosis of the first single gene defect (cystic fibrosis), earlier prenatal diagnosis by coeloentesis and transcervical flushing, further clarification of the specific gene defects (for example, fragile X), and new diagnostic techniques such as chromosome painting.

There is also a problem in that the well organised presentation of data in a book of this type tends to give a false impression to the reader that preimplantation diagnosis of genetic disease is a straightforward, painless, and highly successful procedure. The book is a useful and informative introduction to the field of genetic diagnosis which is highly recommended. Readers should be aware that it is not an introductory or "easy read" text and it is not a "quick reference" book.
