The papers are grouped under the following general headings: replication of nucleic acids (including work on DNA and RNA polymerases); intermediates in DNA synthesis (with much on the significance of ligase action); repair of DNA; genetics of replication; structure of replicating DNA (with the concept that DNA can be circular as well as linear); origins of replication; bacterial mating; replication and the cell membrane; replication of temperate viruses and its regulation. The volume is rounded off by a summary by Hotchkiss on 'Metabolism and growth of gene substance: 1968'; this should be widely read. He points out that x-ray analysis is valuable for the structure of DNA in all its forms, but is less helpful for understanding the protein of the essential DNA-protein complexes because of the readiness with which the protein molecule 'breathes, unfolds and changes in water...'. His survey highlights the importance of polynucleotide ligases in joining breaks in single strands of DNA, and how they interact with the polymerases; he also emphasizes differences between what is observed in the test-tube and what occurs in life. Indeed, it is sobering for an old-fashioned geneticist to see how much 'genetics' is based on bacteria, viruses, and bacteriophage, which, in the old sense, had no 'honest' chromosomes until the new Genetics redefined the gene. Now, with such volumes as this, we know a great deal about 'the gene' (new currency); I wonder whether we know much more than we did about the 'old gene', which sat on a chromosome in a mammalian or plant cell, and showed position effect and true recombination?

J. CHAYEN

As authoritative up-to-date reviews of various aspects of medical genetics, this series has now become well-established, and the present volume maintains a high standard of scholarship.

D. H. Carr reviews the present state of chromosomal abnormalities in clinical medicine. Clearly such a review, in the space allowed, could not be exhaustive and the author has therefore concentrated on the most significant contributions. Carr has been responsible for much of the work on chromosome abnormalities in spontaneous abortions and this subject is dealt with in some depth. As the author points out, in view of the high abortion rate of chromosomally abnormal zygotes before the 16th week of gestation, it is perhaps questionable whether or not amniocentesis for the purposes of antenatal diagnosis should be attempted sooner than this. Carr also discusses the recent interesting observation that certain types of chromosomal abnormality (polyplody and XO) are particularly frequent among abortions of women who become pregnant shortly after discontinuing oral contraception.

The review of the genetics of the gastro-intestinal system by R. B. McConnell clearly illustrates that simple Mendelian principles cannot explain the familial incidences of many of these disorders. The association between gastro-intestinal pathology and the blood groups is reviewed in detail, and what is so far known about genetic factors in Hirschsprung's disease, Crohn's disease, ulcerative colitis, and the various types of polyposis is also discussed. In contrast to the gastro-intestinal disorders, the biochemical mechanisms underlying many of the hereditary disorders of the thyroid gland have now been identified. However, in G. R. Fraser's review of this subject it is clear that there are still many unsolved problems. The pathogenesis of the majority of thyroid abnormalities is extremely complex involving both genetic and environmental factors, and there is so far no satisfactory explanation for the fact that all forms of thyroid disease are more frequent or more severe in females than in males.

Immune mechanisms directed either to one's own antigens or to foreign antigens are reviewed, respectively, by P. J. Fialkow (genetic aspects of autoimmunity) and F. H. Bach (genetic and practical considerations of histocompatibility in man). Both these chapters are thought provoking. On the one hand Fialkow discusses the increased frequency of tissue-specific antibodies in affected individuals and their relatives with various so-called autoimmune diseases (perhaps a better term would be 'autoresistant'). Bach considers possible genetic interpretations for the results of leucocyte typing studies in families.

Jacob and Monod in 1961 proposed a theory, based on their work on bacteria, which emphasized the importance of regulatory genes in controlling gene activity. J. C. Dreyfus considers in detail the application of these ideas to human genetics, and concludes that the vast majority of hereditary biochemical disorders in man are due to mutations of structural genes. Dreyfus found only two diseases which might be attributed to control gene mutations: the erythrocytic porphyrias which might be due to a regulator negative mutation, and von Willebrand's disease which might be due to a super-repressor type mutation.

In a final chapter, E. Eggermont reviews the genetics of intestinal carbohydrate intolerance. Sucrose intolerance with a deficiency of sucrase as well as isomaltase, maltase, and y-amylase is perhaps comparable to oroticaciduria in which there is a deficiency of orotidyl acid pyrophosphorylase, and decarboxylase. Both these disorders might be interpreted as being due to operon mutations and this is discussed by J. C. Dreyfus.

This book can be unreservedly recommended to anyone interested in medical genetics.

A. E. H. EMERY

This is the second edition of that highly readable little book on human cytogenetics aimed at the clinician and
written by a clinician. Dr. Valentine has largely succeeded in his efforts to write a most readable book on human cytogenetics specifically for a clinical audience. As a result, there is much simplification and a few errors. The book has, however, been completely rewritten and some chapters considerably enlarged—in particular, Chapter 1. This is useful as some background on molecular genetics is essential. The section on the XYY condition is also expanded and is particularly valuable, drawing as it does on Valentine’s personal experience with four of these children detected as newborn infants and in particular the difficult problem of what to tell the parents. There is, however, one major criticism; no mention is made anywhere of the international notation for describing chromosome abnormalities which was accepted by an International Conference in Chicago in 1966. This is now accepted and is being used by most major journals and should be known to everyone likely to read the cytogenetic literature. An appendix giving this would have been desirable.

In general the book is well produced and the illustrations good, some of the diagrams may not be as clear as they might have been, but no glaring errors are evident. The book is readable, short enough to be read by a busy clinician and should be compulsory reading for many clinicians who, for the filmiest of reasons, request karyotypes from their local laboratory; if only a few of these unnecessary requests are eliminated the book will have been justified. The book is a reasonable price and to be recommended to the audience for which it was intended.

JOHN L. HAMERTON

This is the long-awaited English translation of the French classic ‘Les Chromosomes Humains’. The French work appeared in 1965, and it is a great pity that apart from one chapter no attempt has been made to bring the present volume up to date. The tremendous volume of work done in the past four years, which is thus omitted, makes this a far less valuable publication than it might have been. However, having said this, it is still valuable to have this classic work available in the English language. It is a pity that more care was not taken with the translation. The English is often clumsy and hard to read, due, in places, to an almost literal translation from the French. The only chapter to be brought up to date is Chapter 13 which deals with monozygotic twins with unlike chromosome complements. This is an interesting phenomenon originally described by Turpin and his co-workers, but is essentially an extension of the principle of non-disjunction followed by uniovular twinning and does not raise any new points of principle. The recent work on the XXY males is not mentioned nor has the bibliography been brought up to date to any degree.

The book is well produced with excellent photographs and diagrams. As it is, it will be a useful addition to the human cytogenetics literature. A little forethought could have made it invaluable.

JOHN L. HAMERTON

Chromosomes and Genes. The Biological Basis of Heredity. (Contemporary Science Paperbacks No. 30.) By P. C. Koller. (Pp. vii + 144; 37 figures + 19 tables. 7s. 6d.) Edinburgh: Oliver & Boyd.

This is an excellent little book aimed at the informed layman and student. It covers, in easily understood language, cytogenetics and cell biology, and is to be recommended to all who wish a closer understanding of these subjects which form the background to the many exciting studies in human heredity covered in the last two chapters.

The author is to be congratulated on the clarity of the presentation of a great deal of complex data in a fairly compact space and in a language that should be understandable to all.

JOHN L. HAMERTON

This is a useful little book for students and others requiring a simple and inexpensive text on cytogenetics. The basic principles are clearly covered in the first four chapters.

Chapter 5 deals with alteration in chromosome constitution, while the remaining chapters are concerned with sex determination, chromosome analysis and techniques, and the essentials of chromosome mechanics. This is a useful little book for students requiring a simple basic text in cytogenetics. In view of its importance it is a pity that more examples were not taken from human cytogenetics. This would have even merited a chapter of its own and would have made this book more valuable to the present-day student, particularly as many of the openings in cytogenetics are in this discipline.

JOHN L. HAMERTON

This Rumanian treatise on the genetic aspects of endocrine disturbances has been written in the conviction that most endocrinopathies are genetically determined, and that such affections are of outstanding importance clinically. The English reader will appreciate the English summary of 15 pages, the illustrations, and the extensive and full references to the literature. The text covers systematically the different endocrines (though it
